

How the agent operates

chkpmcpaws chat "how many hosts are configured?"

- 1 You ask a plain-English question about the estate.
- 2 The agent authenticates (Cognito JWT) and lists every tool the gateway exposes.
- 3 Claude, on Bedrock, decides which Check Point tool to call and with what arguments.
- 4 The gateway invokes the runtime; the @chkp server queries the real estate.
- 5 The result returns to the model, which reasons again — looping 3–5 as needed.
- 6 You get an answer grounded in real tool output — not a guess.

An optional AI guardrail is your choice: the AWS-native gateway engine (default) governs tool calls here, or Check Point AI Guardrail (Lakera) screens the prompt before the model runs. The same loop runs in your terminal or hosted on AgentCore Runtime (chkp_agent); with `--session`, AgentCore Memory recalls facts across sessions.
